[Diagonal Wiring Architecture for Integrated Circuits]

Cross Reference To Related Applications

This application is a continuation application of United States Patent Application Serial No. 09/733,104, entitled "Multi-Directional Wiring on a Single Metal Layer", filed on December 7,2000.

Background of Invention

[0001] An integrated circuit ("IC") is a semiconductor device that includes many electronic components (*e.g.* , transistors, resistors, diodes, etc.). These components are often interconnected to form multiple circuit components (*e.g.* , gates, cells, memory units, arithmetic units, controllers, decoders, etc.) on the IC. The electronic and circuit components of IC's are jointly referred to below as "components."An IC also includes multiple layers of metal and/or polysilicon wiring that interconnect its electronic and circuit components. For instance, many ICs are currently fabricated with five metal layers. In theory, the wiring on the metal layers can be all-angle wiring (*i.e.* , the wiring can be in any arbitrary direction). Such all-angle wiring is commonly referred to as Euclidean wiring. In practice, however, each metal layer typically has a preferred wiring direction, and the preferred direction alternates between successive metal layers. Many ICs use the Manhattan wiring model that specifies alternating layers of preferred-direction horizontal and vertical wiring. In this wiring model, the majority of the wires can only make 90 ° turns. However, occasional diagonal jogs are sometimes allowed on the preferred horizontal and vertical layers.

[0002] The distance of the wiring on the metal layers determines the propagation delay exhibited during operation of the circuit components. In turn, the propagation delay

introduced in a circuit directly impacts the operational speed of the circuit (*i.e.* , the greater the propagation delay the slower the operational speed of the circuit). The length of the wire determines the amount of propagation delay introduced into a circuit (*i.e.* , the longer the wire the greater the propagation delay). In addition, when circuit connections are routed between metal layers, using mechanisms referred to as "vias", a significant amount of additional propagation delay is introduced. Accordingly, it is desirable to reduce the length of wires necessary to interconnect electronic components in an IC to reduce the propagation delay and to enhance the operational speed of the IC. It is also desirable to minimize the number of circuit connections routed between metal layers to further reduce the propagation delay.

Summary of Invention

[0003] Wiring geometries in metal layers use horizontal or vertical wires with a preferred diagonal direction. A "zag conductor", as used herein, is a Manhattan directional wire coupled to a diagonal wire in a region with preferred diagonal wiring. In one embodiment, a metal layer has a region with an area of at least 100 microns. The region includes a plurality of preferred diagonal direction conductors and at least one zag conductor to interconnect points on the integrated circuit. The preferred diagonal direction conductors are deposited in a preferred diagonal direction, such that a preferred diagonal direction defines a direction relative to the boundaries of the integrated circuit. The zag conductor is deposited in a Manhattan direction, and is coupled to one of the preferred diagonal direction conductors so as to interconnect points on the integrated circuit using at least one zag conductor and at least one preferred diagonal direction conductor.

[0004] In another embodiment, a metal layer has a plurality of conductors deposited in a preferred diagonal direction, such that the preferred diagonal direction defines a direction, relative to the boundaries of the integrated circuit, for at least fifty percent of conductors on the metal layer. At least one zag conductor is deposited in a Manhattan direction and is coupled to a conductor deposited in a diagonal direction, so as to interconnect points on the integrated circuit using at least one zag conductor and at least one preferred diagonal direction conductor. The diagonal directions include any direction that is not 0 or 90 degrees, such as octalinear or hexalinear

wiring directions.

[0005] As used herein, a "zig-zag" geometry connotes a combination of at least one wire deposited in a Manhattan direction coupled to at least one wire deposited in a diagonal direction. The use of zig-zag wiring permits simulating Euclidean directional wiring through use of Manhattan wiring and diagonal wiring (e.g., 45 degrees, 60 degrees, etc.). In one embodiment, a "zig-zag" geometry comprises pairs of a Manhattan wire connected to a diagonal wire. Any Euclidean wiring angle may be achieved by selection of the proper wire lengths for the Manhattan and diagonal wire combinations.

[0006] Each pair of conductors, used to simulate the wiring direction, includes two wires. The first wire, which has a first wire length with first and second ends, is deposited in a Manhattan direction relative to the boundaries of the integrated circuit. The second wire, which has a second wire length with first and second ends, is deposited in a diagonal direction, and is coupled to the second end of the first wire. The effective wiring direction of the pairs of conductors comprises an angle, A, measured relative to the boundaries of the integrated circuit. Specifically, the effective wiring direction is defined by the expression $\tan A = Y/X$, wherein, Y defines a line segment with a distance that starts from the second end of the second wire in the last conductor pair and ends at an intersection with a line segment propagated from the first end of the first wire and in the direction of the first wire, and X comprises a distance, measured in the direction of the first wire, that starts from the first end of the first wire and ends with the intersection of the Y line segment. The Manhattan direction includes either a horizontal or vertical direction. In some embodiments, the diagonal direction includes an octilinear or hexalinear directions. The pairs of conductors may be configured, essentially in parallel, to generate tracks of conductor on a metal layer in the simulated direction.

[0007] Diagonal wiring directions in integrated circuits are simulated with wires deposited in purely Manhattan directions (e.g., horizontal and vertical directions). A metal layer of an integrated circuit contains at least two pairs of conductors to interconnect one or more points on the integrated circuit. As used herein, a conductor comprises one or more wires, and a wire comprises a continuous segment deposited in a single

TOP SECRET 92786-00001

direction. Each pair of conductors, used to simulate the wiring direction, includes two wires. The first wire, which has a first wire length with first and second ends, is deposited in a first Manhattan direction relative to the boundaries of the integrated circuit. The second wire, which has a second wire length with first and second ends, is deposited in a second Manhattan direction, and is coupled to the second end of the first wire. The first Manhattan direction is different than the second Manhattan direction. The effective wiring direction of the pairs of conductors comprises an angle, A, measured relative to the boundaries of the integrated circuit. Specifically, the effective wiring direction is defined by the expression $\tan A = Y/X$, wherein, Y defines a line segment with a distance that starts from the second end of the second wire in the last conductor pair and ends at an intersection with a line segment propagated from the first end of the first wire and in the direction of the first wire, and X comprises a distance, measured in the direction of the first wire, that starts from the first end of the first wire and ends with the intersection of the Y line segment.

- [0008] The first Manhattan direction includes either a horizontal or vertical direction, and the second Manhattan direction includes either a horizontal or vertical direction, opposite from the first Manhattan direction. In one embodiment, the Manhattan directional wires are configured to simulate a 45 degree wiring direction, and, in another embodiment, the Manhattan directional wires are configured to simulate a 60 degree wiring direction. The pairs of conductors may be configured, essentially in parallel, to generate tracks of conductor on a metal layer in the simulated direction.

Detailed Description

[0034] The present invention utilizes diagonal wiring in a "preferred" direction. For purposes of nomenclature, a "preferred" direction is defined as the direction that at least 40 percent of the wires are configured. For example, the preferred direction may be Manhattan (i.e., horizontal or vertical) or diagonal. As used herein, diagonal wiring is defined as metal conductors configured at various Euclidean angles. Interconnect lines are considered "diagonal" if they form an angle other than zero or ninety degrees with respect to the layout boundary of the IC. In preferred embodiments, diagonal wiring consists of wires deposited at plus 45 degrees or minus 45 degrees (referred to herein as "octalinear"). This wiring architecture is referred to as octagonal wiring in order to convey that an interconnect line can traverse in eight separate directions from any given point. Wires deposited at any combination of 60 degrees and 30 degrees are referred to herein as "hexalinear." For purposes of simplicity, hexalinear wiring is illustrated as plus 60 or minus 60; however, any combination of 30 degrees and 60 degrees may be used. Although the use of the diagonal wiring in the present invention is described in conjunction with wires arranged at plus 45, minus 45, as well as combinations of 30 degrees and 60 degrees, any angle offset from zero and 90 degrees (horizontal or vertical) may be used as diagonal wiring without deviating from the spirit or scope of the invention.

2025 RELEASE UNDER E.O. 14176

[0035] In general, metal layers on integrated circuit are typically organized in perpendicular metal layer pairs. The use of perpendicular metal layer pairs minimizes wiring distances by minimizing the number of layers a wire or via must traverse to get to a layer with wires disposed in an opposite direction (*e.g.* , vertical to horizontal). In addition, the use of perpendicular wiring, which eliminates wires routed in parallel, reduces electrical coupling between metal layers and minimizes noise interference.

[0036] Some embodiments of the present invention are described using "complementary" pairs. As used herein, complementary pairs refer to two wiring layers with a preferred wiring direction perpendicular to one another. For example, a complement to a vertical wiring layer is a horizontal wiring layer. In diagonal wiring, a complementary direction to a plus 45 degree wiring direction is a minus 45 degree wiring direction. Similarly, a complementary direction to a minus 60 degree wiring direction is a plus 30 degree wiring direction, a complementary direction to a minus 30 degree wiring direction is a plus 60 degree wiring direction, and a complementary direction to a plus 60 degree wiring direction is a minus 60 degree wiring direction, etc.

[0037] Figure 1a illustrates multiple metal layers that employ diagonal wiring. In this architecture, the IC layout utilizes horizontal, vertical, and 45 ° diagonal interconnect lines. The horizontal lines are the lines that are parallel to the x-axis (*i.e.* , the horizontal lines are at 0 ° to the x-axis and parallel to the length of the layout). The vertical lines are the lines that are perpendicular to the x-axis (*i.e.* , the vertical lines are at 90 ° to the x-axis). In this architecture, one set of diagonal lines (layer 3) are at +45 ° with respect to the length of the IC layout, while another set (layer 4) are at -45 ° with respect to the length of the IC layout.

[0038] A top view of integrated circuit 100 is shown in Figure 1a. For this example, there are four metal or wire layers. As shown in Figure 1a, wires deposited in layer one are designated with short dashed lines, wires deposited in layer two are designated with longer dashed lines, wires deposited in layer 3 are designated with a solid line, and wires deposited in layer four are designated with alternating long-short dashed lines. The wires in a layer do not touch or cross other wires in that layer. As shown in Figure 1a, layer "1" wires, such as wire 130, have a predominate or "preferred" horizontal

direction. The wires deposited in layer "1" are situated horizontally such that the wires run parallel to the top and bottom of integrated circuit 100. The wires deposited in layer "2" have a preferred vertical direction (*e.g.* , wire 120 is situated in a vertical direction relative to the top and bottom of the integrated circuit chip 100). Thus, for this example, metal layers one and two are Manhattan layers with horizontal and vertical preferred directions, respectively.

[0039] For the example of Figure 1a, layers "3" and "4" employ diagonal wiring. Specifically, layer "3" has a preferred diagonal direction (*i.e.* , plus 45 degrees) relative to the top and bottom of integrated circuit 100. Wire 140 is an example layer "3" wire oriented in a diagonal direction. Layer "4" has a preferred diagonal direction that is minus 45 degrees relative to the top and bottom of integrated circuit 100. Wire 150 is example of a layer "4" wire situated at minus 45 degrees.

[0040] The example of Figure 1a also includes a plurality of vias. In general, the vias provide an electrical conductor between metal layers to permit routing between the metal layers in the integrated circuit. The circles illustrated in Figure 1a depict vias connecting wires on different layers. For example, via 110 electrically connects a vertical wire on layer "2" to a diagonal wire on layer "4." Similarly, several vias are shown in the example of Figure 1a to couple wires: between Manhattan layers, between diagonal layers, and between Manhattan and diagonal layers. The use of diagonal wiring more efficiently routes wires in the integrated circuit by reducing the length of the wire.

[0041] Figure 1b illustrates another example of an integrated circuit that employs diagonal wiring. The top view of integrated circuit 155 shows a single metal or wire layer. For this example, the preferred direction for the metal layer is plus 45 degrees. As the diagonal direction is a "preferred" direction, wires oriented in directions other than a diagonal direction are also permitted. Specifically, integrated circuit 155 includes wire 160, oriented in a horizontal direction, to couple or connect two diagonal wires situated on different diagonal "tracks." Similarly, horizontal wire 180 couples two diagonal wires in two different tracks. Also, for this example, in addition to horizontal wires in a metal layer with a preferred diagonal direction, a vertical wire

170 is disposed.

[0042] The diagonal wiring of the present invention may be implemented on a gridless system. Typically, wires are placed on a grid to define spacing between potential "tracks" for placement of wires on that layer. For example, a grid may define spacing between rows of tracks in a metal layer that has a preferred horizontal direction. Thus, grids are used to define minimum spacing between wires or "tracks" on a metal layer in the preferred direction. For the example of Figure 1b, wires are not evenly spaced on a grid (*i.e.*, the wires are not aligned on a grid). Although the spacing between wires maintains the minimum spacing specified by design rules, the spacing is not necessarily uniform across the metal layer in a gridless system. For example, the spacing between wires 190 and 192 is greater than the diagonal spacing between wires 192 and 194. This wire placement illustrates the orientation of diagonal wires on a gridless system.

[0043] In one embodiment, the use of a horizontal or vertical wire in a layer with a preferred diagonal direction is defined as a "zag." The use of a zag minimizes obstruction of adjacent "tracks" by not creating an obstruction in one track to detour a wire to another track. Thus, the use of zags minimizes the number of vias required.

[0044] Figure 2a illustrates one embodiment for a complementary octalinear pair. For this embodiment, layer "n" has a preferred direction of plus 45 degrees as illustrated by a plurality of "tracks" drawn across the area of the metal layer. As a complement to layer "n", layer "n+1" consists of a preferred direction of minus 45 degrees. The preferred direction of minus 45 degrees is also illustrated by a plurality of tracks drawn at minus 45 degrees on layer "n+1" in Figure 2a.

[0045] Figure 2b illustrates another embodiment for a complementary octalinear metal layer pair. For this embodiment, layer "n" has a preferred direction of minus 45 degrees. The complementary layer, layer "n+1", has a preferred direction of plus 45 degrees. Again, the preferred direction is illustrated by a plurality of track lines drawn in the preferred direction.

[0046] Figure 3a illustrates another example of complementary diagonal pair layers. The

complementary diagonal pairs of Figures 2a and 2b are situated at plus/minus 45 degrees, whereas the complementary diagonal pairs of Figures 3a and 3b are arranged in plus/minus 60 degree pairs. The embodiment of Figure 3a illustrates layer "n" with a preferred direction of plus 60 degrees, and illustrates complementary layer "n+1" with a preferred direction of minus 60 degrees. The embodiment of Figure 3b illustrates another complementary pair, wherein diagonal wiring is the preferred direction. For this embodiment, the complementary pairs are situated such that layer "n" has a preferred direction of minus 60 degrees, and layer "n+1" has a preferred direction of plus 60 degrees.

[0047] Figures 4a-b illustrate multi-layer wiring configurations. Specifically, Figure 4a illustrates an integrated circuit implemented using octalinear wiring geometries for metal layers 1 and 2. For this embodiment, level "1" has a preferred octalinear direction, and level "2" has a preferred octalinear direction complementary to the octalinear direction of level "1".

[0048] A side view of integrated circuit 400 reveals various configurations of metal layers (i.e., "n", "m", and "k" layers). The variables "n", "m" and "k" may include any integer value greater than 2. In one embodiment, in addition to the octalinear wiring geometries for metal layers 1 and 2, the integrated circuit includes complementary octalinear layer pairs for layers "n" and "n-1". For example, the preferred direction of level "n" may be plus 45 degrees and the preferred direction of level "n-1" may be minus 45 degrees, or the preferred direction of level "n" may be minus 45 degrees, and the preferred direction of level "n-1" may be plus 45 degrees. In one embodiment, if n is equal to 4, then layers "3" and "4" also have preferred octalinear directions situated as a complementary pair (i.e., the preferred direction of level "3" is complementary to the preferred direction of level "4"). Additional embodiments for single octalinear layer geometries may also be employed. For example, layer 3 may employ an octalinear wiring geometry without a complementary octalinear wiring layer.

[0049] Figure 4a also illustrates embodiments that include one or more layers of Manhattan wiring geometries. For these embodiments, complementary Manhattan

layer pairs for layers "m" and "m-1" are deposited on top of metal layers 1 and 2. The preferred direction of level "m" may be 90 degrees and the preferred direction of level "m-1" may be 0 degrees, or the preferred direction of level "m" may be 0 degrees and the preferred direction of level "m-1" may be 90 degrees. For example, if m is equal to 4, then layers "3" and "4" have preferred Manhattan direction layers situated as a complementary pair. Embodiments that employ single Manhattan layer geometries are also shown. For example, layer 3 may employ a Manhattan wiring geometry without a complementary Manhattan wiring layer.

[0050] Figure 4a also illustrates embodiments that include one or more layers of hexalinear wiring geometries. For these embodiments, complementary hexalinear layer pairs for layers "k" and "k-1" are deposited on top of metal layers 1 and 2. The preferred direction of level "k" may be plus 60 degrees and the preferred direction of level "k-1" may be minus 60 degrees, or the preferred direction of level "k" may be minus 60 degrees and the preferred direction of level "k-1" may be plus 60 degrees. For example, if m is equal to 4, then layers "3" and "4" have preferred hexalinear direction layers situated as a complementary pair. Embodiments that employ single hexalinear layer geometries are also shown. For example, layer 3 may employ a hexalinear wiring geometry without a complementary hexalinear wiring layer.

[0051] Figure 4b illustrates an integrated circuit implemented using hexalinear wiring geometries for metal layers 1 and 2. For this embodiment, level "1" has a preferred hexalinear direction, and level "2" has a preferred hexalinear direction complementary to the hexalinear direction of level "1". A side view of the integrated circuit shown in 4b reveals various configurations of metal layers (i.e., "n", "m", and "k" layers). The variables "n", "m" and "k" may include any integer value greater than 2. In one embodiment, in addition to the hexalinear wiring geometries for metal layers 1 and 2, the integrated circuit includes complementary octalinear layer pairs for layers "n" and "n-1." For example, the preferred direction of level "n" may be plus 45 degrees and the preferred direction of level "n-1" may be minus 45 degrees, or the preferred direction of level "n" may be minus 45 degrees, and the preferred direction of level "n-1" may be plus 45 degrees. In one embodiment, if n is equal to 4, then layers "3" and "4" have preferred octalinear directions situated as a complementary pair. Additional

embodiments for single octilinear layer geometries may also be employed. For example, layer 3 may employ an octilinear wiring geometry without a complementary octilinear wiring layer.

[0052] Figure 4b also illustrates embodiments that include one or more layers of Manhattan wiring geometries. For these embodiments, complementary Manhattan layer pairs for layers "m" and "m-1" are deposited on top of metal layers 1 and 2. The preferred direction of level "m" may be 90 degrees and the preferred direction of level "m-1" may be 0 degrees, or the preferred direction of level "m" may be 0 degrees and the preferred direction of level "m-1" may be 90 degrees. For example, if m is equal to 4, then layers "3" and "4" have preferred Manhattan direction layers situated as a complementary pair. Embodiments that employ single Manhattan layer geometries are also shown. For example, layer 3 may employ a Manhattan wiring geometry without a complementary Manhattan wiring layer.

[0053] Figure 4b also illustrates embodiments that include one or more layers of hexilinear wiring geometries. For these embodiments, complementary hexilinear layer pairs for layers "k" and "k-1" are deposited on top of metal layers 1 and 2. The preferred direction of level "k" may be plus 60 degrees and the preferred direction of level "k-1" may be minus 60 degrees, or the preferred direction of level "k" may be minus 60 degrees and the preferred direction of level "k-1" may be plus 60 degrees. For example, if m is equal to 4, then layers "3" and "4" have preferred hexilinear direction layers situated as a complementary pair. Embodiments that employ single hexilinear layer geometries are also shown. For example, layer 3 may employ a hexilinear wiring geometry without a complementary hexilinear wiring layer.

[0054] Figure 5a is a block diagram illustrating one embodiment for combining one or more diagonal wiring layers with legacy Manhattan layers. Existing integrated circuit technology uses Manhattan (i.e., vertical and horizontal) wiring geometries. Typically, integrated circuit sub blocks licensed for use by third parties incorporate levels one through three using Manhattan wiring schemes. Thus, layers "1" through "3" that employ Manhattan wiring schemes are referred to herein as legacy Manhattan geometries.

the preferred direction of level "m-1" may be 90 degrees. For example, if m is equal to 7, then layers "6" and "7" have preferred Manhattan direction layers situated as a complementary pair. Embodiments that employ single Manhattan layer geometries are also shown. For example, layer 6 may employ a Manhattan wiring geometry without a complementary Manhattan wiring layer.

[0058] Figure 5b also illustrates embodiments that include one or more layers of hexalinear wiring geometries. For these embodiments, complementary hexalinear layer pairs for layers "k" and "k-1" are deposited on top of metal layers 1-5. The preferred direction of level "k" may be plus 60 degrees and the preferred direction of level "k-1" may be minus 60 degrees, or the preferred direction of level "k" may be plus 60 degrees and the preferred direction of level "k-1" may be minus 60 degrees. For example, if k is equal to 7, then layers "6" and "7" have preferred hexalinear direction layers situated as a complementary pair. Embodiments that employ single hexalinear layer geometries are also shown. For example, layer 6 may employ a hexalinear wiring geometry without a complementary hexalinear wiring layer.

[0059] Figure 6a illustrates one embodiment for a legacy Manhattan metal layer configuration. For this embodiment, layer "1" has a preferred horizontal direction, layer "2" has a preferred vertical direction, and layer "3" has a preferred horizontal direction. As such, the preferred direction of layer "2" is complementary to the preferred direction of layer "1". Similarly, the preferred direction of layer "3" is complementary to the preferred direction of layer "2". Figure 6b illustrates a second legacy Manhattan wiring geometry. For this embodiment, the first layer has a preferred vertical direction as shown by the vertical lines in Figure 6b. Layer "2", complementary to layer "1", has a preferred horizontal direction. Layer "3", complementary to layer "2", has a preferred vertical direction.

[0060] Figure 6c illustrates a third legacy Manhattan wiring geometry. For this embodiment, the first layer has a preferred horizontal direction as shown by the horizontal "track" lines in Figure 6c. Layer "2", complementary to layer "1", has a preferred vertical direction. Layer "3" has a preferred vertical direction, similar to layer 2.

0968176-060301
T080909-9278960

- [0061] Figure 6d illustrates a fourth legacy Manhattan wiring geometry. For this embodiment, the first layer has a preferred vertical direction as shown by the vertical "track" lines in Figure 6d. Layer "2", complementary to layer "1", has a preferred horizontal direction. Layer "3" has a preferred horizontal direction, similar to layer 2.
- [0062] Figure 7 illustrates one embodiment for combining hexalinear wiring layers with legacy Manhattan layers. As shown in Figure 7, metal layers "1", "2" and "3" have preferred Manhattan wiring directions. In some embodiments, the preferred direction of layer "2" is complementary to the preferred direction of layers "1" and "3" to form a geometry of horizontal – vertical – horizontal or vertical – horizontal – vertical. For the embodiment of Figure 7, metal layers "4" and "5" are configured as hexalinear complementary pairs for the preferred wiring direction. In one embodiment, layer "4" has a preferred direction of plus 60 degrees and layer "5" has a preferred direction of minus 60 degrees. In another embodiment, layer "4" has a preferred direction of minus 60 degrees, and layer "5" has a preferred direction of plus 60 degrees.
- [0063] The integrated circuit of Figure 7 is shown as having "n", "m" or "k" metal layers. Thus, any number of additional diagonal metal layers may be added on in addition to layer "5", as needed to fulfill routing requirements. The variables "n", "m" and "k" may include any integer value greater than 6.
- [0064] In one embodiment shown in Figure 7, in addition to the Manhattan and hexalinear wiring geometries for metal layers 1–5, the integrated circuit includes complementary octalinear layer pairs for layers "n" and "n–1." For example, the preferred direction of level "n" may be plus 45 degrees and the preferred direction of level "n–1" may be minus 45 degrees, or the preferred direction of level "n" may be minus 45 degrees, and the preferred direction of level "n–1" may be plus 45 degrees. In one embodiment, if n is equal to 7, then layers "7" and "6" have preferred octalinear directions, situated as a complementary pair (i.e., the preferred direction of level "6" is complementary to the preferred direction of level "7"). Additional embodiments for single octalinear layer geometries may also be employed. For example, layer 6 may employ an octalinear wiring geometry without a complementary octalinear wiring layer.

[0065] Figure 7 also illustrates embodiments that include one or more layers of Manhattan wiring geometries. For these embodiments, complementary Manhattan layer pairs for layers "m" and "m-1" are deposited on top of metal layers 1-5. The preferred direction of level "m" may be 90 degrees and the preferred direction of level "m-1" may be 0 degrees, or the preferred direction of level "m" may be 0 degrees and the preferred direction of level "m-1" may be 90 degrees. For example, if m is equal to 7, then layers "6" and "7" have preferred Manhattan direction layers situated as a complementary pair. Embodiments that employ single Manhattan layer geometries are also shown. For example, layer 6 may employ a Manhattan wiring geometry without a complementary Manhattan wiring layer.

[0066] Figure 7 also illustrates embodiments that include one or more layers of hexalinear wiring geometries. For these embodiments, complementary hexalinear layer pairs for layers "k" and "k-1" are deposited on top of metal layers 1-5. The preferred direction of level "k" may be plus 60 degrees and the preferred direction of level "k-1" may be minus 60 degrees, or the preferred direction of level "k" may be plus 60 degrees and the preferred direction of level "k-1" may be minus 60 degrees. For example, if k is equal to 7, then layers "6" and "7" have preferred hexalinear direction layers situated as a complementary pair. Embodiments that employ single hexalinear layer geometries are also shown. For example, layer 6 may employ a hexalinear wiring geometry without a complementary hexalinear wiring layer.

[0067] Figure 8 illustrates another embodiment for combining diagonal wiring layers with legacy Manhattan layers. As shown in Figure 8, layers "1", "2" and "3" have a preferred Manhattan direction. In one embodiment, layer two is configured as the complement of layers "1" and "3." In one embodiment of Figure 8, layers "4" and "5" consist of a complementary diagonal pair for the preferred wiring direction (i.e., either hexalinear or octalinear complementary pairs). In another embodiment, layers "4" and "5" consist of diagonal wiring directions that are not complementary.

[0068] Metal layer "6" has a preferred Manhattan wiring direction. In one embodiment, metal layer "6" has a preferred Manhattan wiring direction that complements the preferred Manhattan wiring direction of level three. For example, if the wiring

directions of layers "1", "2" and "3" consist of a horizontal vertical – horizontal configuration, respectively, then Manhattan layer six has a preferred vertical direction. Or, if the wiring directions of layers "1", "2", and "3" consist of a vertical horizontal – vertical configuration, respectively, then Manhattan layer "6" has a preferred horizontal direction. The configuration of adding a complementary Manhattan layer to level "6" (i.e., complementary to level "3") maximizes the availability of wiring in a direction opposite from level "3." Figure 8 also illustrates additional embodiments for adding additional layers above layer "6." For this embodiment, additional layers may be added above layer "6" to form either diagonal complementary pairs at levels "n" and "n-1" or to form Manhattan complementary pairs at levels "k" and "k-1", wherein "n" and "k" are even integers, six or greater. Embodiments that employ single diagonal or Manhattan layer geometries are also shown. For example, layer 7 may employ a diagonal wiring geometry without a complementary diagonal wiring layer.

[0069] One advantage of the Manhattan and diagonal wiring geometries of Figure 8 is that the transition in signal routing direction from a diagonal routing layer to a Manhattan routing layer is better leveraged. For example, to change direction from metal layer 5 to a vertical routing direction requires only routing the connection to metal layer 6, rather than routing the connection all the way down to metal layer "2." Because a substantial cost is incurred for routing between layers and a cost is incurred in switching routing directions by requiring a jump to a different layer, minimizing the cost of switching directions benefits the ease of design of the chip.

[0070] Figure 9 illustrates another embodiment for combining diagonal wiring layers with legacy Manhattan layers. The first six layers of integrated circuit 900 are configured with preferred directions as the first six layers of Figure 8. However, layer "7" has a preferred Manhattan direction that is complementary to the preferred Manhattan direction of layer "6." This embodiment has the advantage of providing another complementary Manhattan layer above layer "6" to minimize routing distances between wires coupled between layers "6" and "7." As shown in Figure 9, any combination of diagonal or Manhattan layers or complementary pairs of layers may be disposed above layer "7." Figure 10 illustrates an example metal layer with multiple preferred directions. A metal layer may be divided into sections or blocks, such that

each block or section has a preferred wiring direction. In Figure 10, a top view of integrated circuit 1000 exposing a metal layer is shown. For this example, the metal layer is divided into five sections, labeled 1010, 1020, 1030, 1040 and 1050. Section 1010 has a preferred diagonal direction (*i.e.* , a preferred direction of plus 45 degrees). Although section 1010 has a preferred octilinear direction, wire 1012 is disposed in a horizontal direction. Section 1030 also has a preferred octilinear direction of minus 45 degrees. Also, section 1040 has a preferred hexilinear direction of plus 60 degrees. For this example, wire 1042 is disposed in a horizontal direction. The example of Figure 10 also includes Manhattan direction wiring for sections 1020 and 1050. Specifically, section 1020 has a preferred vertical direction, whereas section 1050 has a preferred horizontal direction. Similar to sections 1010 and 1040, sections 1020 and 1050 have wires disposed in a direction other than the preferred direction. For purposes of illustration, the sections shown in Figure 10 include only a few wires. However, a section, as defined herein, is a contiguous area of the IC that contains at least one thousand wires.

[0071] An integrated circuit with multiple sections having different preferred directions has application for use in IP blocks. For example, an IP block may include four metal layers comprising Manhattan wiring geometries. For this example, the use of different preferred wiring directions in different sections permits implementing diagonal wiring geometries in areas of metal layer four outside the IP block. Other applications for implementing different preferred wiring directions in different sections may be realized.

[0072] Typically, pre-designed blocks ("IP blocks") integrated into integrated circuits require that metal layers disposed above the IP blocks do not route wires above those blocks. This requirement ensures that the operation of the IP blocks is not altered by noise coupled from metal layers above the IP blocks. For example, a memory, integrated as a pre-configured block, may be highly sensitive to voltage swings. To ensure proper operation of the memory block, a requirement may prohibit the placement of any wires above the memory block.

[0073] In general, diagonal wiring geometries provide noise immunity from Manhattan

wiring geometries. The use of diagonal wiring in the present invention permits routing wires in areas above IP blocks. Since the IP blocks utilize Manhattan wiring geometries, the use of diagonal wires in metal layers above the IP blocks do not result in noise coupling between the wires on the metal layer(s) and the wires on the IP block. This supports a hierarchical design approach. In a hierarchical design approach, wires in a subsection of the IC are routed independent of other areas of the IC. For example, an IP block, with Manhattan directional wires routed independent of other portions of the IC, may be integrated into an IC employing diagonal wires without noise coupling concerns.

[0074] Figure 11 is an example of using diagonal wiring in metal layers disposed above IP blocks. For this example, an integrated circuit 1100 includes pre-configured or IP blocks 1110, 1120 and 1130. The IP blocks 1110, 1120 and 1130 are self-contained within layers "1", "2" and "3" of integrated circuit 1100.

[0075] Figure 11 shows a top view of a wiring layer above layer three (*i.e.* , layer "4" or above). As shown in Figure 11, the use of diagonal wiring permits routing diagonal wires above IP blocks 1110, 1120 and 1130. Because the preferred wiring direction in this metal layer is not either horizontal or vertical, electrical emanations from the diagonal wires do not directly coupled to the wire layers in the IP blocks, and thus do not cause a degradation in circuit performance. The wiring layer shown in Figure 11 is also divided into two preferred wiring directions. Section 1150 has a plus 45 preferred wiring direction, and section 1140 has a preferred wiring direction of minus 45 degrees.

[0076] There are several advantages in using diagonal wiring geometries. When routing in Manhattan directions, the area reached with a given total wire length may be described as a diamond around the source of the wire. Assuming a wire length of one, a wire reaches a distance of +1 or -1 on the X or Y direction or along the edges connecting those points. This area within a distance of 1 creates the diamond shape. The total area of this region within routing distance "1" is two. The maximum distance from the center reached by a 45 degree direction is (.5 times the square route of 2.0) (*i.e.* , .5 in the X direction plus .5 in the Y direction reaches the center point).

[0077] When routing wires at 45 degrees, a distance of "1" from the center along the diagonals is reached. Thus, the use of diagonal wiring effectively extends the space reached by roots of length "1." The area of this region within routing distance 1 is 2.8284. If an area is larger within the same wiring distance of a point, then the total wire length on a chip is reduced, assuming the additional area within the same wiring distances is leveraged. If the wire length on integrated circuits is reduced, then: 1) the propagation delay through the shorter wires is less, reducing the complexity of the chip design; 2) the congestion encountered when routing wires on a chip is reduced if the total amount of wire on a chip is also reduced, thereby enhancing the design of the chip; and 3) the size of the integrated circuit chip may be reduced by reducing the total mount of wires on the chip, thus decreasing costs of manufacture.

[0078] One advantage in implementing wiring geometries where the lower metal layers employ Manhattan routing directions is to directly leverage existing design components in a new layout scheme. Typically, integrated circuits are generally composed of two types of logic blocks: small cells implementing simple logic functions, and large functional blocks to implement specific functionalities. The large blocks are used because they are much more efficient at implementing their specific functionality, as opposed to implementing the same functionality using a large number of small cells. These two types of logic blocks are generally implemented using the three metal layers configured in Manhattan wiring directions. Small cells typically employ metal layers "1", and in some cases, metal layer "2." Large logic blocks typically employ metal layers 1, 2, and 3. Thus, because existing wiring directions commonly in use today consist of Manhattan directions on metal layers 1, 2, and 3, there is an advantage in designing new integrated circuit chips with new wiring geometries that incorporate Manhattan layers. Thus, employing diagonal wiring geometries on metal layers of both metal layer 3 maintains compatibility with existing cell libraries in large functional blocks.

[0079] Figure 12A illustrates a prior art configuration for routing two wires that switch tracks. For this example, wires 1210, 1200, 1235 and 1245 are routed on a single layer, with a preferred horizontal wiring direction. Specifically, a wire 1200 on a first layer switches tracks to wire 1235, also on the first layer. Wire 1210, also on the first

layer, switches track to wire 1245 on that same layer. Using Manhattan wiring geometries, wire 1210 is routed to a different layer that employs a vertical wiring direction. Specifically, for this example, the routing on the vertical layer occurs on wire 1250. To connect wire 1245, a second via is used to jump from the vertical wiring layer of wire 1250 back to the horizontal wiring layer with wire 1245. As shown in Figure 12A, 2 this routing requires two vias.

[0080] Figure 12A also routes wire 1200 through a via to wire 1220 on a vertical layer. In addition, a via is used to route to wire 1220 to wire 1230, located on a horizontal layer. A further layer transition and via are required to route wire 1230 to wire 1240, located on a vertical layer. To complete the connection to the original horizontal layer, wire 1240 is coupled to wire 1235 using a fourth via. As illustrated by this example, a total of 6 vias are required to alternate tracks on a single layer.

[0081] Figure 12B illustrates an example for switching tracks using diagonal wiring. Similar to Figure 12A, wires 1250, 1260, 1265, and 1275 are deposited on a single layer, with a preferred horizontal wiring direction. For this example, to route wire 1265 to wire 1275, a single diagonal wire, 1270, is used. The diagonal wire in the example of Figure 12B is defined as a zag. To route wire 1250 to wire 1260, a via is used to route the connection to diagonal wire 1255 and on a different layer. A second via couples wire 1255 to wire 1260 on the original layer.

[0082] Figure 13 illustrates another embodiment for use of diagonal wiring in conjunction with Manhattan wiring. As shown in Figure 13, layer "n" and layer "n+1" are adjacent metal layers. For this embodiment, layer "n" has wires deposited horizontally, and layer "n+1" has wires deposited diagonally. Wires 1300 and 1310 on layer "n" are connected through wire 1320 on layer "n+1" as shown.

[0083] As illustrated in Figures 12B and 13, using diagonal wiring, only two vias are required to switch tracks between two wires. In the prior art technique illustrated in Figure 12A, a total of 6 vias on two additional layers were used to accomplish this.

[0084] As used herein, a "zig-zag" geometry connotes a combination of at least one wire deposited in a Manhattan direction coupled to at least one wire deposited in a diagonal

direction. The use of zig-zag wiring permits simulating Euclidean directional wiring through use of Manhattan wiring and diagonal wiring (*e.g.* , 45 degrees, 60 degrees, etc.). In one embodiment, a "zig-zag" geometry comprises pairs of a Manhattan wire connected to a diagonal wire. Figure 14 illustrates one embodiment for a "zig-zag" wiring geometry. In general, any Euclidean wiring angle may be achieved by selection of the proper wire lengths for the Manhattan and diagonal wire combinations. The arrow in Figure 14 designates the direction simulated by the zig-zag configuration. For the example of Figure 14, wire 1410, deposited in a horizontal direction, is connected to wire 1420, deposited in a diagonal direction (*e.g.* , 45 degrees). In turn, wire 1430, deposited in a horizontal direction, couples wire 1420 and wire 1440, deposited in a diagonal direction. The angle, A , is defined by the following relationship: $\tan A = Y/X$, wherein, Y is the vertical distance and X is the horizontal distance. Using this configuration of alternating horizontal and diagonal wires, any angle A may be obtained.

[0085] Diagonal wiring may also be simulated with wires deposited in a purely horizontal and vertical direction. Figure 15 illustrates an example metal layer that simulates diagonal wires with wires deposited in Manhattan directions. As shown in Figure 15, a series of wires, arranged in tracks, form a diagonal direction. For this example, the angle between the point designated 1510 and the point designated 1520 is 45 degrees. This technique permits simulating a diagonal wiring direction, through horizontal and vertical wires, by selecting the appropriate lengths for the horizontal and vertical wires. Thus, any diagonal wiring direction may be simulated through this technique. In one embodiment, a plurality of horizontal and vertical wire routings on layer 1500 are situated in parallel to generate tracks of simulated diagonal wires as shown in Figure 15.

[0086] The diagonal wiring geometries of the present invention also have application for use in routing clock signals. Figure 16 illustrates an example of routing clock signals using diagonal wires. For this example, a clock 1610 generates a clock signal for timing on integrated circuit 1600. Wire 1620 conducts the clock signal from the clock 1610 on a first metal layer. In turn, wire 1630 carries the clock signal on a second layer, and wire 1640 carries the clock signal on a third layer.

[0087] The use of diagonal wiring to conduct clock signals significantly reduces the amount of power required to propagate the clock signal. In addition, the use of diagonal wiring reduces the length of wire necessary to conduct clock signals, thereby decreasing clock delay and clock skew.

[0088] Although the present invention has been described in terms of specific exemplary embodiments, it will be appreciated that various modifications and alterations might be made by those skilled in the art without departing from the spirit and scope of the invention.
